Software Design for Data Science

Virtual Environments

Melissa Winstanley University of Washington February 20, 2025

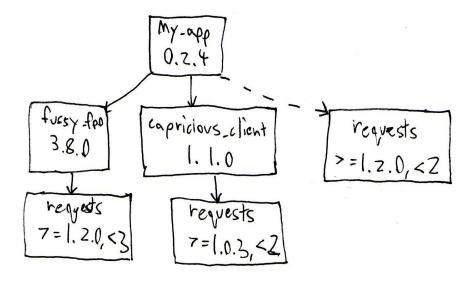

The problem

- Melissa is working on a project.
- Melissa installs scikit-learn to use in the project.
- Melissa writes great tests, which pass!
- Baisakhi wants to contribute to the GitHub repository
- Baisakhi clones the repository
- Nothing works for Baisakhi because she hasn't installed scikit-learn (or any other packages required by the project)!

The problem: dependency hell

- Dependency chains (A depends on B depends on C ...)
- Conflicting dependencies
- Circular dependencies (A depends on B depends on A)

The problem, continued

- Baisakhi and Melissa may be using different systems
 - Mac
 - Windows
- Baisakhi and Melissa may have different versions of Python
- Baisakhi and Melissa may have different Python packages installed

- We need a way so that the code will always work for both Baisakhi & Melissa
 - And for anyone else who wants to use the package!

Abstraction

Hiding the details of the implementation (ie the infrastructure)

Abstraction for Melissa & Baisakhi

We want to hide away the details of the underlying system and make it so that when Melissa & Baisakhi work on the project, they see the same things:

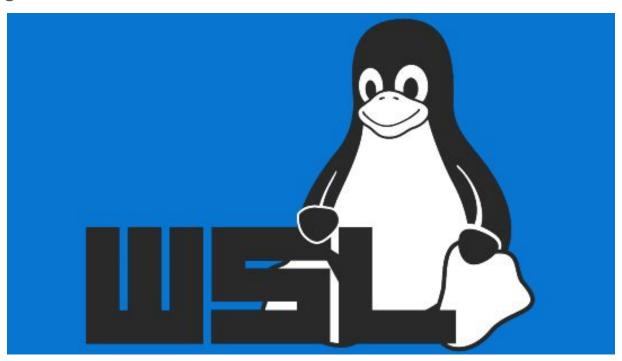

- The same Python version
- The same packages
- The same package versions
- o etc

Virtualization

The act of creating a virtual (rather than actual) version of something at the same abstraction level, such as an environment, process, operating system, or hardware.

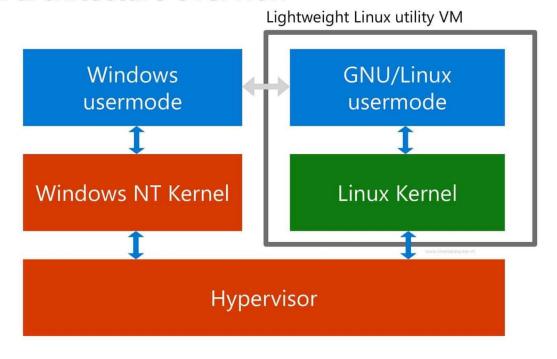

Virtualization example

Hardware, eg VirtualBox

Virtual Machines - WSL

WSL 2 architecture overview

Virtual Machines - VirtualBox

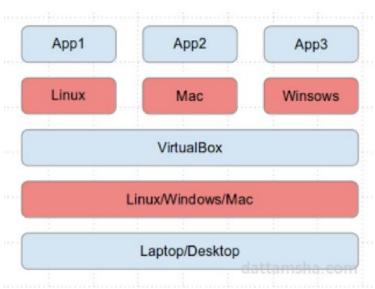

- https://www.virtualbox.org
- Open source, free, and just works

Uses processor level virtualization instructions to operate guest operating

system

Choose the right guest type

- Allocate enough resources
- Always install guest additions

Virtual Machines - EC2

- Start with a base operating system image
- Install software you want
- Create any data volumes, etc. you want
- Halt the instance
- Make an Amazon Machine Image
- Publish
- Pay for S3 storage, use a paid AMI model...

Virtualization of Python environments

- For Melissa & Baisakhi, we need to virtualize environment
 - Python version
 - Package dependency versions
- Separate your computer's Python/packages from the project's Python/packages
- Multiple options
 - o venv
 - virtualenv
 - conda

Conda Virtual Environments

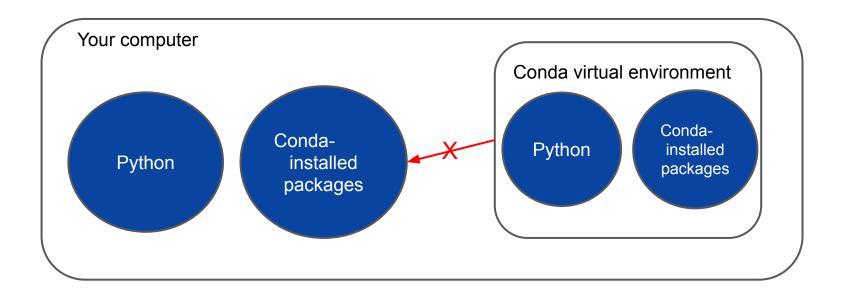

- conda create -n <name> <options>
 - Creates a new environment with the given name
- conda activate <name>
 - "Activates" the environment ("switches into it", like a git branch)
- Anything you do now will affect only the *current* environment
 - Installing packages
 - Updating package versions
- conda deactivate
 - o "Deactivates" the environment ("switches off of it", like switching back to git's main branch)
- conda remove --name <name> --all
 - Deletes the environment
- conda info --envs
 - Lists all the environments that exist

Exercise: Create a Python Virtual Environment

- Create a conda environment for SPECIFICALLY Python 3.8.15
 - o Hint: use conda create
 - O Hint: don't forget to activate the environment!
 - Hint: check the options on the conda create command to see how to set Python version
- Start up a Jupyter notebook and prove that it's Python 3.8.15
 - Hint: remember that the new environment doesn't have access to your global packages!
 - Hint: check out the platform module for how you might access the Python version

Python Virtual Environments

What just happened?

Sharing your virtual environment

- conda env export > environment.yml
 - Encodes all of the Python and package information in your environment to environment.yml
 - o Format is YAML, a human-readable data serialization language
- conda env create -f environment.yml
 - o Creates a new environment from a file, with all of its specified packages
- conda env update -f environment.yml
 - Updates your environment to match the environment.yml file
 - Useful if your teammates are adding packages do it after you pull
 - Useful to upgrade packages
- Always commit the environment.yml file to the repository!

Exercise: Create an environment.yml file

For your Python 3.8.15 environment:

- 1. Create an environment.yml file: conda env export > environment.yml
- 2. Delete the existing environment so that we can practice creating from yml:

 conda deactivate

 conda remove --name <name> --all
- 3. Recreate the environment from the yml file:

 conda env create -f environment.yml
- 4. Prove that it works start up your Jupyter notebook again.

Generated environment.yml

```
name: py3815 \ Name for the environment
                     Where Conda can find packages
channels:
  - defaults (default location)
                                                                All the packages that
dependencies:
                                                                conda has installed in
    anyio=3.5.0=py38hca03da5 0
  - appnope=0.1.2=py38hca03d\overline{a}5 1001
                                                                this environment
  - argon2-cffi=21.3.0=pyhd3eb\overline{1}b0 0
  - argon2-cffi-bindings=21.2.0=p\overline{y}38h1a28f6b 0
                                                                This includes transitive
  - asttokens=2.0.5=pyhd3eb1b0 0
                                                                 dependencies (ie the
  - attrs=22.1.0=py38hca03da5 \overline{0}
                                                             rerepakkages ଏନ୍ନାr system.
viron ଅନ୍ତନ୍ଧନ୍ତ ଓନ୍ନାr system.
  - babel=2.11.0=py38hca03da5_0
    backcall=0.2.0=pyhd3eb1b0_0
    beautifulsoup4=4.11.1=py3\overline{8}hca03da5 0
                                                            lot negeseary for other people
  - bleach=4.1.0=pyhd3eb1b0 0
     brotlipy=0.7.0=py38h1a2\overline{8}f6b 1002
prefix: /Users/melissawins/enley/en/miniconda3/envs/py3815
```

Simpler environment.yml

```
name: py3815
channels:
  - defaults

    No prefix

dependencies:

    Only explicitly needed

  - jupyter=1.0.0
                               dependencies
  - notebook=6.5.2
  - python=3.8.15
                               What does this number mean?
```

Semantic Package Versioning

Also known as "semver"

NOT ALL PACKAGES ADHERE TO THIS THOUGH! Do your research.

Major version number This changes when the

package has
BREAKING CHANGES

1

Minor version number

6|5|2

This changes when the package has new backwards-compatible features

Extra stuff

Extra info about release or build (eg for specifying "pre-release" or beta release)

Patch version number

This changes when the package has bug fixes

What I would probably do

```
name: py3815

channels:
    - defaults
dependencies:
    - jupyter=1
    - notebook=6
    - python=3.8

These two packages adhere to semantic versioning.

This way I automatically get any new versions just by doing conda env update

Python doesn't adhere to semantic versioning
```

You don't HAVE to do it this way - use more specific package versions if you like! You can also omit package versions (everything after the "="), although it's less safe.

What about pip?

If you use pip to manage packages:

- environment.yml => requirements.txtLooks similar!
- Can create from the environment in a similar way

```
pip freeze > requirements.txt
```

Can reinstall all the requirements into the current environment

```
pip install -r requirements.txt
```

- This does NOT create a new environment
- You can combine environment.yml (for the environment) with requirements.txt (for managing packages with pip) if you like

Adding pip to environment.yml

```
name: py3815
channels:
  - defaults
dependencies:
  - jupyter=1
  - notebook=6
  - python=3.8
                                   pip dependencies by adding a
                                600 Putter another pipe, then
  - pip
                                indenting an extra level, then
  - pip:
                                adding the pip dependencies
     - matplotlib
     - pandas
```

Or with requirements.txt

```
name: py3815
channels:
  - defaults
dependencies:
  - jupyter=1
  - notebook=6
  - python=3.8
  - pip
  - pip:
    - -r requirements.txt
```

Tell conda to load pip dependencies from requirements.txt

Exercise: Simplify your environment.yml

For your Python 3.8.15 environment:

- 1. Simplify your environment.yml file.
 - Remove any unnecessary packages.
 - Simplify the version numbers if you like.
- 2. Update your environment.

conda env update -f environment.yml

3. Prove that it works - start up your Jupyter notebook again.

What about other dependencies?

- Conda environments are for Python & Python packages
- If you need to download other tools or infrastructure, you'll have to do that in a separate script or with a different version manager.

Exercise: create a virtual environment for your project

- 1. Create an environment for your team's project.
- 2. Create an environment.yml file for the environment.

 Include any packages that you need to make your code work.
- 3. Commit, create a PR, and merge the change.
- 4. Make sure everyone on the team can create the environment from the file.
- 5. Include instructions for how to use the environment file in your documentation (README or somewhere in the docs folder).
